

Wheelspeeds overview

Distance is one of the most important channels used in Toolbox and Toolset and is fundamental for features like **Qualifying Mode**. The value of distance is derived from the integral of speed. Therefore, the setup of wheelspeed strategies is critical to make sure that the speed and distance values generated are consistent and correct.

The **Wheelspeed** node is used to configure the wheelspeed inputs and the speed and distance outputs.

Select wheelspeed input type

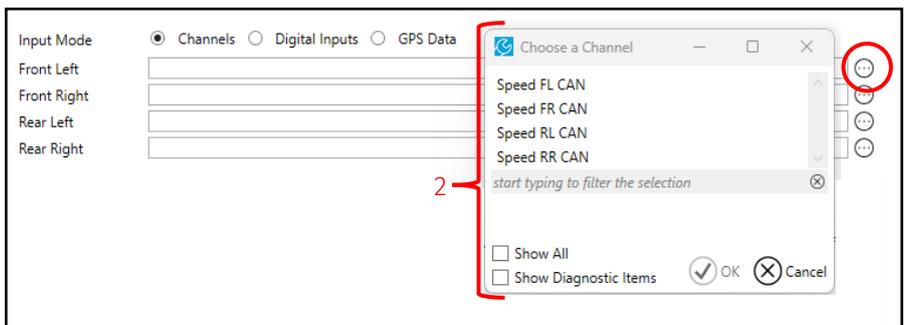

First, configure the wheelspeed inputs. Select the source of speed for each wheel from either a Channel or Digital Input, or vehicle speed from GPS data.

- **Channel** – Use for a channel with units of ‘speed’, such as a channel being received over CAN from an ECU or other device.
- **Digital Inputs** – Use if rotational sensors or DF11i wheelspeed sensors are configured on the [Sensors](#) node.
- **GPS Data** – Use if speed is being decoded from GPS data sourced from the [NMEA 0183 Decode](#) node.

Channel inputs

Configure inputs

If you use channel inputs, click the ‘browse’ tool to select the channel inputs (1), and then select the required channel from the menu (2).

Note: – You must configure the channel with units of ‘speed’. Channels with other units are not available to select.

Processing

Next, select how the individual wheelspeed inputs are combined to calculate the vehicle speed and distance. Individual wheelspeeds are first combined to produce front and rear axle speeds. The front and rear axle speeds are combined to produce overall speed and distance channels.

See Wheelspeed strategy for more information about wheelspeed processing strategy.

Select the chassis strategy (the values from which the front and rear axles are averaged) from the **Chassis Strategy** dropdown menu.

| | | |
|---------------------|-------------------|--|
| Chassis Strategy | Axle Average | <i>The values from the front and rear axles will be averaged.</i> |
| Front Axle Strategy | Axle Average | <i>The values from the left and right wheels will be averaged.</i> |
| Rear Axle Strategy | Front Axle Only | <i>The values from the left and right wheels will be averaged.</i> |
| | Rear Axle Only | |
| | Fastest Axle | |
| | Slowest Axle | |
| | Front Wheel Drive | |
| | Rear Wheel Drive | |

Then select the front and rear axle strategies from the dropdown menus.

| | | |
|---------------------|------------------|--|
| Chassis Strategy | Axle Average | <i>The values from the front and rear axles will be averaged.</i> |
| Front Axle Strategy | Average | <i>The values from the left and right wheels will be averaged.</i> |
| Rear Axle Strategy | Average | <i>The values from the left and right wheels will be averaged.</i> |
| | Left Wheel Only | |
| | Right Wheel Only | |
| | Fastest Wheel | |
| | Slowest Wheel | |

Generated channels

Enter a name for the distance and speed channels generated from the processed inputs in the text boxes.

Digital inputs

Configure inputs

If you use digital inputs, you must select the inputs for each wheel (1), specify the sensor type (2), the number of triggers per rotation (3), and the tire diameter (4). If digital inputs are not configured, you can use the shortcut to the **Hardware Settings** node (5) (see [Hardware Settings](#)).

Input Mode Channels Digital Inputs GPS Data

| | | | | | |
|-------------|------------|----------------------|---|------|---|
| | | 1 | 2 | 3 | 4 |
| Front Left | Digital 01 | Active (Hall Effect) | 8 | 0.66 | |
| Front Right | Digital 02 | Active (Hall Effect) | 8 | 0.66 | |
| Rear Left | Digital 03 | Active (Hall Effect) | 8 | 0.66 | |
| Rear Right | Digital 04 | Active (Hall Effect) | 8 | 0.66 | |
| | | | | m | |

5

Processing

Next select how the individual wheelspeed inputs are combined to calculate the vehicle speed and distance. Individual wheel speeds are first combined to produce front and rear axle speeds. The front and rear axle speeds are combined to produce overall speed and distance channels.

See [Wheelspeed strategy](#) for more information about wheelspeed processing strategy.

Select the chassis strategy (the values from which the front and rear axles are averaged) from the **Chassis Strategy** dropdown menu.

| | | |
|---------------------|-------------------|---|
| Chassis Strategy | Axle Average | The values from the front and rear axles will be averaged. |
| Front Axle Strategy | Axle Average | The values from the left and right wheels will be averaged. |
| Rear Axle Strategy | Front Axle Only | The values from the left and right wheels will be averaged. |
| | Rear Axle Only | |
| | Fastest Axle | |
| | Slowest Axle | |
| | Front Wheel Drive | |
| | Rear Wheel Drive | |

Then select the front and rear axle strategies from the dropdown menus.

| | | |
|---------------------|------------------|---|
| Chassis Strategy | Axle Average | The values from the front and rear axles will be averaged. |
| Front Axle Strategy | Average | The values from the left and right wheels will be averaged. |
| Rear Axle Strategy | Average | The values from the left and right wheels will be averaged. |
| | Left Wheel Only | |
| | Right Wheel Only | |
| | Fastest Wheel | |
| | Slowest Wheel | |

Generated channels

You can then name the channels generated from the processed inputs. When you use digital inputs, there is greater functionality and, therefore, more generated channels. Enter names for the output channels for the wheel speed, angular velocity, triggers, and tire diameter of all wheel inputs.

GPS data

Configure inputs

If you use GPS data, select the GPS speed channel (sourced from the [NMEA 0183 Decode](#)) (1) and configure the strategy for when the speed is valid (2).

Input Mode Channels Digital Inputs GPS Data

Speed ⋮ 1

Speed valid when ⋮ Car is ⋮ 2

Processing

When the GPS signal is invalid, use the **Maintain last value** option to determine whether the speed value is held at the last known value, or select zero speed with the **Assume zero** option.

| | |
|--|--|
| Processing | |
| Select how the speed data is to be processed in the cases where the value of the speed channel is not valid. | |
| Strategy | <input checked="" type="radio"/> Maintain last value <input type="radio"/> Assume zero |

Generated channels

You can then name the distance and speed channels generated from the processed inputs.

Odometer

An odometer channel (a total distance channel stored in non-volatile memory) is also generated. Enter a name for the odometer (1). Click **Add Trip** to add a 'trip meter' channel (2) and add a name for the channel (3). You can also use a to reset the trip meter (see [Buttons](#)) (4). Use the 'bin' tool to delete a trip meter channel (5).

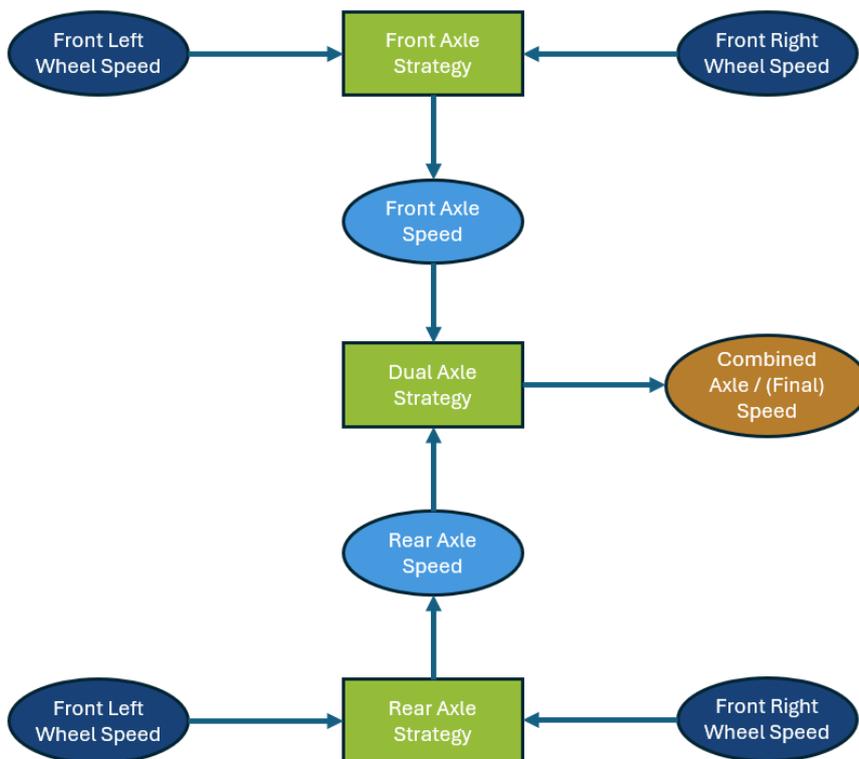

Odometer

Provide a channel name for the odometer.

- 1 Channel Name Odometer
- 2 (+) Add Trip (-)
- 3 Channel Name Trip Distance
- 4 Reset Button Odometer Button Press Release Click Hold Long Hold
- 5 (-)

Wheelspeed strategy

The following flow chart shows how the wheel speed strategies are combined to output the final speed value. Ellipses represent a true, measured, speed and rectangular shapes represent numerical processing or a calculation.

A table of the processing strategies available in Toolset is shown below:

| | Strategy | Description |
|----------------------|-------------------|--|
| Single axle strategy | Left Wheel | Uses the value of the axle left wheel only |
| | Right Wheel | Uses the value of the axle right wheel only |
| | Fastest Wheel | Uses the axle fastest wheel |
| | Slowest Wheel | Uses the axle slowest wheel |
| | Wheel Average | Uses the average of the two wheels |
| Dual axle strategy | Front Axle | Uses the value of the front axle only |
| | Rear Axle | Uses the value of the rear axle only |
| | Fastest Axle | Uses the fastest axle value |
| | Slowest Axle | Uses the slowest axle value |
| | Axle Average | Uses the average of the two axles |
| | Front Wheel Drive | Uses the front axle value under a specified condition (braking), then the rear axle value at all other times |
| | Rear Wheel Drive | Uses the rear axle value under a specified condition (braking), then the front axle value at all other times |

Switch strategies

Some older versions of setup metadata allow switching between strategies (for example, between the left and right wheel on an axle, or between the two axle speeds). In these versions of metadata there is a section to set the switching thresholds.

Switch between left and right wheels when speeds differ by more than % for more than seconds.

Use the front axle when the is more than

The percentage difference in speed is the percentage difference between the fastest and slowest wheel. The percentage difference to the fastest wheel is chosen and not percentage different to slowest wheel because this provides greater accuracy (see the table below):

| FL Wheel Speed (kph) | FR Wheel Speed (kph) | Difference (kph) | Difference to Fastest (%) | Difference to Slowest (%) |
|----------------------|----------------------|------------------|---------------------------|---------------------------|
| 10 | 5 | 5 | $(5/10)*100 = 50$ | $(5/5)*100 = 100$ |
| 100 | 101 | 1 | $(1/101)*100 = 0.9901$ | $(1/100)*100 = 1$ |
| 165 | 170 | 5 | $(5/170)*100 = 2.9412$ | $(5/150)*100 = 3.3333$ |

The time factor is the duration for which the difference statement must be true before the speed channel switches. It is advisable to set the time factor quite low. A good starting setting is below 1-2% and below 0.2 seconds and then amend the settings as required.

Select a strategy

The optimal wheelspeed strategy for a vehicle varies depending on many different variables, and there is no suggestion for the best all round strategy.

The table below outlines some vehicle characteristics together with a suggested approach (actual optimal strategies may vary).

| Vehicle Characteristic | Description | Suggested Approach |
|--------------------------------------|--|--|
| Rear wheelspin likely | Rear Wheels could spin to a value higher than the vehicle speed | Try to use front wheels, depending on Front locking likelihood. Fastest Front Wheel will account for single wheel lockups but not two wheel lockups. |
| Front wheelspin likely | Front Wheels could spin to a value higher than the vehicle speed | Try to use rear wheels, depending on Rear locking likelihood. Fastest Rear would account for rear jacking / single rear wheel lockups. |
| Front locking | Front wheels could drop below representative vehicle speed | If single lockups, can use fastest front wheel, however for double front lockups, the rear wheels should be used if possible. |
| Rear locking / jacking under braking | Rear wheels could drop below representative vehicle speed | If single lockups, can use fastest rear wheel, however for double front lockups, the front wheels should be used if possible. |

Double lockup events tend to affect the speed trace more than wheelspin events, so for a car with both lockups and wheelspin, it can be better to select the axle with wheelspin rather than lockups.
